# "EVALUATING THE 'GRANGER CAUSALITY' WITH REGARD TO MACRO-ECONOMIC VARIABLES AND STOCK PRICE TO ANALYZE THE RESULTANT INFLUENCE"

### **Aayush Goel**

Department of Polymer Science Chemical Technology Delhi Technological University (Formerly Delhi College of Engineering)

In 1991, government of India has introduced a series of policy measures to liberalize its economy to cope up with the ongoing process of globalization all over the world. Relaxation of licensing rule, rationalization of tax structure, enhancement of the ceiling of foreign direct investment and private participation are some of the outcomes of liberalization which has resultant impact in the integration of Indian economy with rest of the economies and has also resulted in increased share in international trade and increased foreign reserve. Stock market assumes a urgent part in developing ventures and business of a nation that in the end influence economy. Its significance has been all around recognized in enterprises and investors viewpoints. Money markets benefit long haul cashflow to recorded firms by pooling stores from various investors and enable them to extend in business and furthermore offers financial specialists contrasting options to put their surplus supports in. The investors precisely watch the execution of stock market by watching the composite market record, before contributing assets. The market record gives an authentic stock market execution, the measuring stick to analyze the execution of individual portfolios and furthermore gives financial specialist to estimating future patterns in the market.

In any case, not at all like develop stock markets of cutting edge nations, the stock markets of rising economies started to grow quickly just in the last two and half decades. While there have been various endeavors to create and settle the stock markets, the developing economies are described as the most unpredictable stock exchanges Moreover, the stock exchanges of rising economies are probably going to be touchy to variables, for example, changes in the level of monetary exercises, changes in the political and worldwide financial condition and furthermore identified with the progressions in other macroeconomic elements.

Financial specialists assess the potential monetary essentials and other firm particular elements/qualities to figure assumptions about the stock markets. In a productive capital market, stock costs alter quickly as indicated by the new data accessible. Thus, the stock costs mirror all data about the stocks. Additionally they reflect desires without bounds exhibitions of corporate

(IJPS) 2017, Vol. No. 4, Jul-Dec

houses. In the event that stock costs mirror these presumptions in genuine, at that point it ought to be utilized as a noteworthy marker for the financial exercises. Thusly, the dynamic connection between stock costs and macroeconomic factors can be utilized to make country's macroeconomic strategies.

With the successive waves of globalization ,capital market cannot be far behind .Therefore, several reforms in the capital market have also been initiated such as opening up of the stock markets to foreign investors, enhancement of the regulatory power of SEBI, trading in derivatives etc. which have resulted in remarkable development in the size and depth of stock markets in India A perception of the macro dynamics of Indian stock market can be helpful for traders, investors policy makers of the country.

Bombay Stock Exchange (BSE) Sensex have been considered as the proxy of the Indian stock market for present study. Bombay Stock Exchange Ltd., Mumbai, was established in 1875 as "The Native Share and Stock Brokers Association" (voluntary non-profit organization), has evolved over the years and is now one of premier exchange in the country.

### **OBJECTIVES OF THE STUDY:**

In this study the major objective is to find out the causal relationship, if any, between stock market and real economic variables. It will shed light on the degree of integration of the two markets and how they affect each other. The specific sets of objectives of the study are as follow:

- 1. To study the causal relationship between Macro-economic variables i.e. Foreign Investment Inflow, Foreign Exchange rate, Gold prices, Crude oil prices, Interest rate and Index for Industrial Production on Stock prices.
- 2. To study the Bi-directional relationship Macro-economic variables and stock prices.

### **Research Methodology**

Research is an unbiased, structured and sequential method of enquiry directed towards a clear implicit and explicit Objective.

### **Research Design**

**Exploratory Research**: Exploratory research is research conducted for a problem that has not been clearly defined. It often occurs before we know enough to make conceptual distinctions or posit an explanatory relationship. Exploratory research helps determine the best research design, data collection method and selection of subjects.

**Causal Research**: In this form of research the marketer tries to determine if the manipulation of one variable, called the independent variable, affects another variable, called the dependent variable. In essence, the marketer is conducting an experiment.

A Multiple regression model is designed to test the effects of Macroeconomic variables on Stock prices:

SP t =  $\alpha$  +  $\beta$ 1 GLD +  $\beta$ 2 IIP+  $\beta$ 3 OIL+  $\beta$ 4 REER+  $\beta$ 5 CMR+  $\beta$ 6FII.....(1)

# **Data collection and Explanatory Variables**

- 1. **Stock Prices:** The empirical investigation is carried out using Monthly data ranging from January 2004 to January 2014. The empirical investigation considers Bombay Stock Exchange (BSE) share price indices as proxy for Indian stock market.
- 2. **Macroeconomic variables:** RBI's official website was used to get data from 2005 to 2014 for the following four macroeconomic variables:

# • Index for Industrial Production (IIP)

Index for Industrial production is utilized as intermediary to quantify the development rate in real part. Industrial production exhibits a measure of general monetary movement in the economy and influences stock prices through its effect on expected future money streams. Along these lines, it is normal that an expansion in Index for Industrial production is decidedly identified with stock prices. The IIP and stock prices are emphatically related in light of the fact that increase in IIP brings about increment in production of industrial sector that leads to increase in profit of industries and corporations. As profit expands, it brings about increment in share costs. In this way, it is relied upon to have positive connection amongst IIP and share prices as indicated by economic theory.

• Crude oil Prices (OIL)

Crude oil is a crucial contribution for production and in this way, the cost of oil is incorporated as an intermediary for real monetary movement. India is to a great extent a shipper of crude oil and subsequently, oil value participates a basic part in Indian economy. It is clear that any key development in oil costs prompts vulnerabilities in the stock market which could convince investors to suspend or postpone their investments. In addition, increment in oil costs brings about higher transportation, generation and warming cost which have negative impact on corporate gaining. Rising fuel costs additionally raise caution about expansion and reduce purchasers optional spending. In this way, the financial danger of

investments increments when there is wide variance in oil cost. In this way for oil bringing in nations like India, an expansion in oil cost will prompt an increment underway expenses and subsequently to diminished future income, prompting a negative effect on money markets. In this manner, an expansion in oil costs in global market implies bring down real monetary movement in all divisions which will make stock prices fall.

# • Gold Price (GLD)

Gold is a substitute venture road for Indian investors. As the gold value rises, Indian investors have a tendency to put less in stock and more in gold to show signs of improvement returns. This outcomes in fall in stock prices. In this way, negative connection exists between gold cost and stock price.

# • Wholesale Price Index (WPI)

A record that measures and tracks the adjustments in cost of merchandise in the phases previously the retail level. Discount cost records (WPIs) report month to month to demonstrate the normal value changes of products sold in mass, and they are a gathering of the pointers that take after development in the economy.

# Data Analysis

With a view to fulfill the stipulated set of targets of the investigation, diverse strategies have been embraced. As a matter of first importance, to satisfy the research objectives, Correlation is utilized to discover if any connection exist between stock market prices and macroeconomic variables. At that point the formal examination is done by looking at the stochastic properties of the factors by utilizing Unit Root Test to test the stationarity of the factors. In this unique circumstance, the generally utilized procedure is Augmented Dickey Fuller (ADF). In the event that the factors don't have unit root issue then Granger causality can be evaluated.

Augmented Dickey Fuller test (ADF) and Granger causality testing have been finished utilizing Eviews.

# **Unit Root Test**

When managing time arrangement information, various econometric issues can impact the estimation of parameters utilizing OLS. Relapsing a period arrangement variable on some other time arrangement variable utilizing Ordinary Least Square (OLS) estimation can acquire a high R<sup>2</sup> in spite of the fact that there is no important connection between them. This circumstance mirrors the issue of spurious relapse between absolutely random factors created by a non-stationary process. The majority of the Macroeconomic information are non-stationary i.e. they tend to display

deterministic or/and stochastic pattern. Thusly, unit root test is directed to complete to test for the request of joining. An arrangement is said to be stationary if mean and fluctuation are time – invariant. A non stationary time arrangement will have a period subordinate mean and fluctuation i.e. information fluctuates with time. In this way, it is inferred that mean [(E (Yt)]] and the fluctuation [Var (Yt)] of Y stays consistent after some time for all t. Since standard relapse investigation require that information arrangement be stationary, it is critical to decide if the arrangement utilized as a part of the relapse procedure is a distinction stationary or incline stationary.

# Augmented Dickey-Fuller Model

Augmented Dickey-Fuller test is utilized to test the stationarity of data. The arrangement could be non stationary as a result of irregular walk or it takes after a particular pattern. To test the non stationarity it is basic to assess a regression that homes a mean, a loafer term (to test for distinction stationarity) and deterministic pattern term (to test for slant stationarity). Following condition checks the stationarity of time arrangement information utilized as a part of the examination:

 $\Delta yt = \beta 1 + \beta 1t + \alpha yt + \gamma \Sigma \Delta yt + \epsilon t \quad \text{Where } t = 1....(2)$ 

Where  $\epsilon$ t is the mistake term in the model of unit root test, with an invalid theory that variable has a unit root, i.e. variable is non-stationary. ADF relapse test for presence of the unit base of yt that speaks to all factor at day and age t. The test for unit root is directed on coefficient of yt-1 in the relapse. On the off chance that the coefficient is essentially not quite the same as zero (under zero) at that point the speculation that y contains a unit root is rejected. The invalid and elective theory for presence of unit root in factor yt is H<sub>0</sub>: $\alpha$ = 0 Versus H<sub>1</sub>: $\alpha$ < 0. Dismissal of the invalid theory indicates stationarity in the arrangement.

On the off chance that ADF test measurement (t-measurement) is less (in the total esteem) than the critical values of t, the invalid speculation of a unit pull can't be rejected for the time arrangement and subsequently, one can presume that the arrangement is a non-stationary at their levels. The unit pull test tests for the presence of a unit root in two cases: with capture just and with block and pattern to consider the effect of the pattern on arrangement.

# **Granger Causality Test**

Causality is a sort of statistical feedback idea which is generally utilized as a part of working of anticipating models. Granger Causality test is a strategy for deciding if one time arrangement is noteworthy in anticipating another. The standard Granger test looks to decide if past estimations of variable predicts changes in another variable. Further, Granger Causality procedure measures the data given by one variable in clarifying the most recent estimation of another variable. What's more, it additionally says that variable Y is Granger caused by factor X if variable X helps with foreseeing

the estimation of variable Y. The invalid speculation that we test for this situation is that the X variable does not Granger cause variable Y and variable Y does not Granger cause variable X. In this manner, one variable (Xt) is said to granger cause another variable (Yt) if the slacked estimations of Xt can foresee Yt and the other way around.

# **Defining Granger Causality**

Assume that we have three terms, Xt , Yt , and Wt , and that we first endeavor to gauge X t+1 utilizing past terms of X t and W t . We at that point endeavor to gauge X t+1 utilizing past terms of X t , Y t , and W t . On the off chance that the second gauge is observed to be more fruitful, as indicated by standard cost functions, at that point the past of Y seems to contain data helping in anticipating X t+1 that isn't in past X t or W t . Specifically, W t could be a vector of conceivable informative factors. In this manner, Y t would "Granger cause" X t+1 if (a) Y t happens before X t+1 ; and (b) it contains data helpful in anticipating X t+1 that isn't found in a gathering of other fitting factors.

......(3)

where p is the most extreme number of lagged perceptions incorporated into the model, the framework A contains the coefficients of the model (i.e., the commitments of each slacked perception to the anticipated estimations of X 1 (t) and X 2 (t), and E 1 and E 2 are residuals (forecast blunders) for each time arrangement. On the off chance that the change of E 1 (or E 2) is lessened by the incorporation of the X 2 (or X1) terms in the first (or second) condition, at that point it is said that X 2 (or X 1) Granger-(G)- causes X 1 (or X 2). At the end of the day, X 2 G-causes X 1 if the coefficients in A 12 are together altogether unique in relation to zero.

### **Hypothesis**

In order to study granger causality between S&P BSE Sensex and Macroeconomic variables following hypothesis were formulated:

1. Null hypothesis (H<sub>0</sub>) for evaluating existence of unit root (Augmented Dickey Fuller Test)

Let X be the macroeconomic variables which include Foreign exchange rate, crude oil prices, interest rate, gold prices, Index for Industrial Production, Foreign Investment Inflow and S&P BSE Sensex.

Ho: Variable X has a unit root

H1: Variable X does not have unit root

(IJPS) 2017, Vol. No. 4, Jul-Dec

e-ISSN: 2455-6270; p-ISSN: 2455-7455

2. Null hypothesis for evaluating granger causality between Macroeconomic variables and S&P BSE Sensex.

Let X include macroeconomic variables (Foreign exchange rate, crude oil prices, interest rate, gold prices, Index for Industrial Production and Foreign Investment Inflow)

Y: S&P BSE Sensex

Ho: X does not granger cause Y

H<sub>1</sub>: X granger causes Y

Ho: Y does not granger cause X

H1: Y granger causes X

### Granger Causality Analysis: Macroeconomic variables and BSE Sensex

The purpose of the present study is to study the relationship that exists between the Macroeconomic variables and the stock prices (S&P BSE Sensex). The study attempts to derive the causality between the macroeconomic variables using various statistical and econometric tools. These tools solve the purpose to represent a true sketch of all these variables which are regarded to be "indicators" of an economy and to demonstrate how they are interrelated and interlinked to each other. The primary purpose of the present study is to study the granger causality among the variables and stock prices. But prior to study of such a causal relationship there is a need to understand whether the variables under study are stationary or not which can be analyzed using Augmented Dickey Fuller test.

### Unit Root Testing using Augmented Dickey Fuller (ADF) Test

When dealing with time series data, a number of econometric issues can influence the estimation of parameters using OLS. Regressing a time series variable on another time series variable using Ordinary Least Square (OLS) estimation can obtain a very high R<sup>2</sup> although there is no meaningful relationship between them. This situation reflects the problem of spurious regression between totally unrelated variables generated by a non- stationary process. Most of the Macroeconomic data are non-stationary i.e. they tend to exhibit deterministic or/and stochastic trend. Therefore, unit root test is conducted to carry out to test for the order of integration. A series is said to be stationary if mean and variance are time –invariant. A non-stationary time series will have a time dependent

41

### INTERNATIONAL JOURNAL OF PROFESSIONAL STUDIES

(IJPS) 2017, Vol. No. 4, Jul-Dec

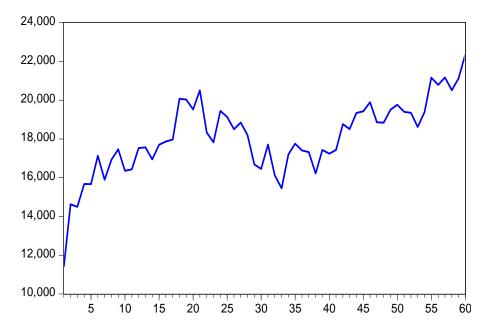

mean and variance i.e. data varies with time. Therefore, it is implied that mean  $[(E (Y_i)]]$  and the variance  $[Var (Y_i)]$  of Y remains constant over time for all t. Since standard regression analysis require that data series be stationary, it is important to determine whether the series used in the regression process is a difference stationary or trend stationary.

In order to check whether the variables are stationary or not Augmented Dickey Fuller (ADF) test has been applied. Since, granger causality testing cannot be done on non-stationary variables

### **Data Analysis and Interpretation**

### 1. BSE Sensex

The S&P BSE SENSEX (S&P Bombay Stock Exchange Sensitive Index), also-called the BSE 30 or simply the SENSEX, is a free-float market capitalization-weighted stock market index of 30 well-established and financially sound companies listed on BSE Ltd..

S&P BSE Sensex

The above graph examines the pattern important for assumption in Augmented Dickey Fuller (ADF) test. The X-axis shows number of observation which is 60 while the Y-axis represents the BSE Sensex. The above figure shows an increasing trend in Sensex i.e. over a period of 5 years the Sensex have been rising. If a trend line is drawn form point '0' it can be observed that the values evolve around the trend line hence it can be proved that as time passes the observations trend upward and hence shows a time trend. On the other hand if we take the sample mean of BSE Sensex it come out to be18087. This value lies between 18,000 and 20,000 on Y-axis. If we draw a horizontal line from here we see that observations evolve around the mean. Thus it can be

(IJPS) 2017, Vol. No. 4, Jul-Dec

concluded that the series evolve around a constant (Mean) and trend. Therefore, we need trend and a constant to check for stationary.

Assumption: To check whether BSE Sensex has a unit root or not we include trend and intercept.

Hypothesis (H<sub>0</sub>): S&P BSE Sensex has a unit Root (non-stationary)

(H1): S&P BSE Sensex does not have a unit root.

(IJPS) 2017, Vol. No. 4, Jul-Dec

On the basis of the graph, it was assumed that BSE Sensex follows a trend and evolve around a constant (Mean). Thus, we check for stationary using trend and intercept. Level represents that there is no difference in the variables. Comparing the critical values of t- statistic with actual values of t- statistic it can be observed that observed value of t- statistic i.e. -3.923146 is greater than the critical values at 1%, 5% and 10% level of significance. Hence it can be concluded that S&P BSE Sensex has a unit root i.e. data is non-stationary

Hence, H<sub>0</sub>: S&P BSE Sensex has a unit root is accepted i.e. BSE Sensex observations are nonstationary. There are 1.70% chances of occurrence of an error. Therefore, we will check at first difference.

At first difference, it can be observed that observed value of t-statistic is less than the critical values of t-statistic. Hence, it can be concluded that S&P BSE Sensex does not have a unit root i.e. the observations of Sensex are stationary. The chance of committing an error is zero. Hence, H<sub>0</sub>: S&P BSE Sensex has a unit root is rejected

Conclusion: H<sub>0</sub>: S&P BSE Sensex has a unit root is rejected. Hence, it can be concluded that BSE Sensex observations are stationary.

#### **Index for Industrial Production**

Index of Industrial Production (IIP) is an abstract number, the magnitude of which represents the status of production in the industrial sector for a given period of time as compared to a reference period of time. IIP is a composite indicator that measures the short-term changes in the volume of production of a basket of industrial products during a given period with respect to that in a chosen base period.

Index for Industrial Production (IIP)

The above graph examines the pattern important for assumption in Augmented Dickey Fuller (ADF) test. The X-axis shows number of observation which is 60 while the Y-axis represents the Index for Industrial Production. The above figure shows that initially there was a continuous increase and decrease in IIP. On the other hand if we take the sample mean of IIP it come out to be 166.6. This value ranges between 160-170 on Y-axis. If we draw a horizontal line from here we see

(IJPS) 2017, Vol. No. 4, Jul-Dec

that observations evolve around the mean. Thus it can be concluded that the series evolve around a constant (Mean) and trend. Therefore, we need trend and a constant to check for stationary.

Assumption: To check whether Index of Industrial production has a unit root or not we include trend and intercept.

Hypothesis (H<sub>0</sub>): Index for Industrial Production has a unit Root (non-stationary)

(H1): Index for Industrial Production does not have a unit root.

At level, observed value of t-statistic -3.722284 is greater than the critical values of t-statistic at 1%, 5% and 10% level of significance. Hence, null hypothesis that Index for Industrial production has a unit root is not rejected i.e. observations of crude oil prices is non-stationary. Moreover, there are 2.89% chances of occurrence of error. Therefore, we will check for stationary at first difference.

At first difference, it can be observed that observed value of t-statistic is less than the critical values of t-statistic. Hence, it can be concluded that IIP does not have a unit root i.e. the observations of IIP are stationary. The chance of committing an error is zero. Hence, H<sub>0</sub>: Index for Industrial Production has a unit root is rejected.

Conclusion: H<sub>0</sub>: Index for Industrial Production has a unit root is rejected. The observations of Index for Industrial Production are stationary.

### 2. <u>Wholesale price index</u>

The Wholesale Price Index (WPI) is the price of a representative basket of wholesale goods. The wholesale price index (WPI) is based on the wholesale price of a few relevant commodities of over 240 commodities available. An index that measures and tracks the changes in price of goods in the stages before the retail level. Wholesale price indexes (WPIs) report monthly to show the average price changes of goods sold in bulk, and they are a group of the indicators that follow growth in the economy.

The above graph examines the pattern important for assumption in Augmented Dickey Fuller (ADF) test. The X-axis shows number of observation which is 60 while the Y-axis represents the Wholesale price index. The above figure shows that initially there was a continuous increase in WPI however maintained a consistent rise and hence the trend which can be noticed is increasing

#### INTERNATIONAL JOURNAL OF PROFESSIONAL STUDIES

(IJPS) 2017, Vol. No. 4, Jul-Dec

one. On the other hand if we take the sample mean of WPI it come out to be155.1067. This value ranges between 150-160 on Y-axis. If we draw a horizontal line from here we see that observations evolve around the mean. Thus it can be concluded that the series evolve around a constant (Mean) and trend. Therefore, we need trend and a constant to check for stationary.

Assumption: To check whether Index of Industrial production has a unit root or not we include trend and intercept.

Hypothesis (H<sub>0</sub>): Index for WPI has a unit Root (non-stationary)

(H<sub>1</sub>): Index for WPI does not have a unit root.

On the basis of the graph, it was assumed that WPI follows a trend and evolve around a constant (Mean). Thus, we check for stationary using trend and intercept. Level represents that there is no difference in the variables. Comparing the critical values of t- statistic with actual values of t- statistic it can be observed that observed value of t- statistic i.e. -2.518430 is greater than the critical values at 1%, 5% and 10% level of significance. Hence it can be concluded that WPI has a unit root i.e. data is non stationary

1% level of Significance= Observed value > Critical value -2.590526> -4.124265

5% level of significance= Observed value> Critical value -2.590526> -4.124265

10% level of significance= observed value> critical value -2.590526> -3.173114

Hence, H<sub>0</sub>: WPI has a unit root is accepted i.e. WPI observations are non stationary. There are 28.61% chances of occurrence of an error. Therefore, we will check at first difference.

At first difference, it can be observed that observed value of t-statistic is less than the critical values of t-statistic. Hence, it can be concluded that WPI does not have a unit root i.e. the observations of WPI are stationary. The chance of committing an error is zero. Hence, Ho: WPI has a unit root is rejected

Conclusion: Ho: WPI has a unit root is rejected. Hence, it can be concluded that WPI observations are stationary.

### 3. Gold Prices

Of all the precious metals, gold is the most popular as an investment. Investors generally buy gold as a hedge or harbor against economic, political, or social fiat currency crises (including investment market declines, burgeoning national debt, currency failure, inflation, war and social unrest).

GOLD-Traded Contracts (in Lots)

(IJPS) 2017, Vol. No. 4, Jul-Dec

e-ISSN: 2455-6270; p-ISSN: 2455-7455

The above graph examines the pattern important for assumption in Augmented Dickey Fuller (ADF) test. The X-axis shows number of observation which is 60 while the Y-axis represents the Gold Prices. The above figure shows an increasing trend in Gold prices i.e. over a period of 5 years the gold prices have been rising. If a trend line is drawn form point '0' it can be observed that the values evolve around the trend line hence it can be proved that as time passes the observations trend upward and hence shows a time trend. On the other hand if we take the sample mean of Gold prices it come out to be 864102.517. This value lies between 800000 and 1200000 on Y-axis. If we draw a horizontal line from here we see that observations evolve around the mean. Thus it can be concluded that the series evolve around a constant (sample Mean) and trend. Therefore, we need trend and a constant to check for stationary.

Assumption: To check whether Gold Prices has a unit root or not we include trend and intercept.

Hypothesis (H<sub>0</sub>): Gold Prices has a unit Root (non-stationary)

(H<sub>1</sub>): Gold Prices does not have a unit root.

On the basis of the graph, it was assumed that GDP follows a trend and evolve around a constant (Mean). Thus, we check for stationary using trend and intercept. Level represents that there is no difference in the variables. By comparing the observed value of t- statistic with critical values of t- statistic it can be observed that observed value of t- statistic i.e. -1.833089 is greater than the critical values at 1%, 5% and 10% level of significance. Hence it can be concluded that GDP has a unit root i.e. data is non-stationary.

Hence, H<sub>0</sub>: GDP has a unit root is accepted i.e. GDP observations are non-stationary. But there are 63.79% chances of occurrence of an error. Therefore, we will check at first difference.

At second difference, it can be observed that observed value of t-statistic is less than the critical values of t-statistic. Hence, it can be concluded that GDP does not have a unit root i.e. the observations of Sensex are stationary. The chance of committing an error is zero.

Therefore, H<sub>0</sub>: GDP has a unit root is rejected. Hence, it can be concluded that GDP observations are stationary.

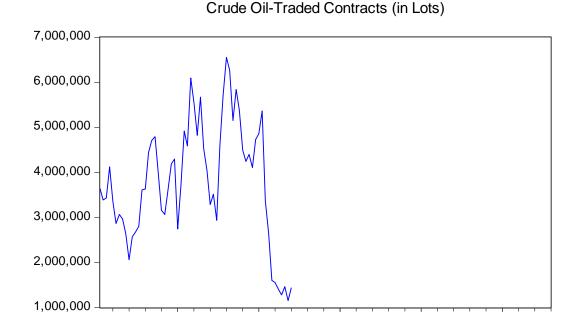

### 5. <u>Crude Oil Prices</u>

A naturally occurring, unrefined petroleum product composed of hydrocarbon deposits. Crude oil can be refined to produce usable products such as gasoline, diesel and various forms of petrochemicals. The fluctuation in the price of crude oil has bearing on inflation as increase in price of crude oil cause prices of petrol, diesel etc to rise thereby raising the cost of transportation and hence have trickledown effect on various industries.

At first difference, it can be observed that observed value of t-statistic is less than the critical values of t-statistic i.e. -7.351958 is less than the critical values at 1%, 5% and 10% level of significance. Hence, it can be concluded that Crude oil prices does not have a unit root i.e. the observations of crude oil prices are stationary. The chance of committing an error is zero. Hence, H<sub>0</sub>: Crude oil price has a unit root is rejected.

**Conclusion:** H<sub>0</sub>: Crude oil price has a unit root is rejected. Thus observations of Crude oil Prices are stationary.

### **Granger Causality Test**

Granger Causality test is a system for deciding if one time arrangement is huge in guaging another. The standard Granger test tries to decide if past estimations of variable predicts changes in another variable. Further, Granger Causality procedure measures the data given by one variable in clarifying the most recent estimation of another variable. Likewise, it additionally says that variable Y is Granger caused by factor X if variable X helps with foreseeing the estimation of variable Y. The invalid speculation that we test for this situation is that the X variable does not Granger cause variable Y and variable Y does not Granger cause variable X. In this way, one variable (Xt) is said to granger cause another variable (Yt) if the slacked estimations of Xt can anticipate Yt and the other way around.

### **Concept of Granger causality**

Assume that we have three terms, X t , Y t , and W t , and that we first endeavor to gauge X t+1 utilizing past terms of X t and W t . We at that point endeavor to figure X t+1 utilizing past terms of X t , Y t , and W t . In the event that the second figure is observed to be more fruitful, as indicated by standard cost capacities, at that point the past of Y seems to contain data helping in estimating X t+1 that isn't in past X t or W t . Specifically, W t could be a vector of conceivable logical factors. Consequently, Y t would "Granger cause" X t+1 if (a) Y t happens before X t+1; and (b) it contains data helpful in determining X t+1 that isn't found in a gathering of other proper factors.

where p is the most extreme number of slacked perceptions incorporated into the model, the framework A contains the coefficients of the model (i.e., the commitments of each slacked perception to the anticipated estimations of X 1 (t) and X 2 (t), and E 1 and E 2 are residuals (expectation mistakes) for each time arrangement. On the off chance that the difference of E 1 (or E 2) is decreased by the consideration of the X 2 (or X1) terms in the first (or second) condition, at that point it is said that X 2 (or X 1) Granger-(G)- causes X 1 (or X 2). At the end of the day, X 2 G-causes X 1 if the coefficients in A 12 are mutually altogether not the same as zero

### 1. Index of Industrial Production and S&P BSE Sensex

Research problem: Whether Index of Industrial Production causes S&P BSE Sensex or/and S&P BSE Sensex causes Index of Industrial Production.

Regression Model for checking Granger causality between two variables is as follow:

• Regression model for IIP causes S&P BSE Sensex

BSE Sensext= $A_{11}$  IIP  $(t-j) + A_{12}$  BSE (t-j) + E(t)

• Regression model for S&P BSE granger causes IIP

e-ISSN: 2455-6270; p-ISSN: 2455-7455

(IJPS) 2017, Vol. No. 4, Jul-Dec

# IIPt= $A_{21}$ IIP (t-j) + $A_{22}$ BSE (t-j) + E (t)

Where, t-j is lagged values or the lag period

E (t): Residual value or the error term

A11, A12, A21, A22 are the coefficients

### Case 1: Index for Industrial production does not granger cause S&P BSE Sensex

Hypothesis (H<sub>0</sub>): IIP does not granger cause S&P BSE Sensex

Null Hypothesis	Lag Values	Observations	F-statistic	Prob.(p value)	Decision
Index for Industrial production does not granger cause BSE Sensex	1	59	7.11405	0.9310	Accept
Index for Industrial production does not granger cause BSE Sensex	2	58	0.05014	0.9511	Accept

According to above table, for lag values ranging from 0 to 2 p-values are always greater than 0.05. Therefore, null hypothesis that index for industrial production does not granger cause S&P BSE Sensex is accepted and IIP does not help in predicting Sensex.

Ho: Index for Industrial Production does not granger cause S&P BSE Sensex is accepted.

### Case 2: S&P BSE Sensex does not granger cause Index for Industrial production

Hypothesis (Ho): S&P BSE Sensex does not granger cause Index for Industrial production

Null Hypothesis	Lag Values	Observations	F-statistic	Prob.(p value)	Decision
S&P BSE Sensex does not granger cause Index for Industrial production	1	59	7.11405	0.0100	Reject

(IJPS) 2017, Vol. No. 4, Jul-Dec

#### e-ISSN: 2455-6270; p-ISSN: 2455-7455

S&P BSE Sensex does not	2	58	2.09950	0.1326	Accept
granger cause Index for					
Industrial production					
_					

According to above table, at lag1 'p'-value is 0.0100 which is less than 0.05. Hence, it can thus be interpreted that S&P BSE Sensex granger cause IIPi.e. IIPcan be predicted using S&P BSE Sensex.

Ho: S&P BSE Sensex does not granger cause Index for Industrial production is rejected.

### Values calculated using Eviews

### AT LAG 1

Pairwise Granger Causality Tests Date: 04/28/15 Time: 17:15 Sample: 2009M04 2014M03 Lags: 1			
Null Hypothesis:	Obs	F-Statistic	Prob.
IIP does not Granger Cause SENSEX SENSEX does not Granger Cause IIP	59	0.00757 7.11405	0.9310 0.0100

### AT LAG 2

Pairwise Granger Causality Tests Date: 04/28/15 Time: 17:15 Sample: 2009M04 2014M03 Lags: 2			
Null Hypothesis:	Obs	F-Statistic	Prob.
IIP does not Granger Cause SENSEX SENSEX does not Granger Cause IIP	58	0.05014 2.09950	0.9511 0.1326

Conclusion: It can be concluded that there exist unidirectional relationship between IIP and BSE Sensex. Since in Case 1 null hypothesis that S&P BSE Sensex does not granger cause IIP is accepted but in case 2 null hypothesis that IIP does not granger cause BSE Sensex is rejected. Therefore, it can be concluded that there exist a relationship between two variables.

### 2. Wholesale price index and Sensex

Research problem: Whether Wholesale price index causes S&P BSE Sensex or/and S&P BSE Sensex causes Wholesale price index.

Regression Model for checking Granger causality between two variables is as follow:

• Regression model for WPI causes S&P BSE Sensex

BSE Sensext= $A_{11}$  WPI (t-j) +  $A_{12}$  BSE (t-j) + E (t)

• Regression model for S&P BSE granger causes IIP

WPIt= A<sub>21</sub> WPI (t-j) + A<sub>22</sub> BSE (t-j) + E (t)

Where, t-j is lagged values or the lag period

E (t): Residual value or the error term

A11, A12, A21, A22 are the coefficients

### Case 1: WPI does not granger cause S&P BSE Sensex.

Hypothesis (H<sub>0</sub>): WPI does not granger cause S&P BSE Sensex

Null Hypothesis	Lag Values	Observations	F-statistic	Prob.(p value)	Decision
Wholesale Price Index does not granger cause BSE Sensex	1	59	3.71840	0.0589	Accept
Wholesale Price Index does not granger cause BSE Sensex	2	58	2.93378	0.0619	Accept
Wholesale Price Index does not granger cause BSE Sensex	4	56	1.03494	0.3992	Accept
Wholesale Price Index does not granger cause BSE Sensex	10	50	0.57929	0.8172	Accept
Wholesale Price Index does not granger cause BSE Sensex	14	46	0.81556	0.6461	Accept

### (H<sub>1</sub>): WPI granger cause S&P BSE Sensex

(IJPS) 2017, Vol. No. 4, Jul-Dec

Wholesale Price Index does not	16	44	0.58408	0.8407	Accept
granger cause BSE Sensex					

According to the above table from lag 1 to lag 16, P-values are more than 5% significant level. Which means that the null hypothesis i.e. WPI does not granger cause BSE Sensex is accepted.

### Case 2: S&P BSE Sensex does not granger cause WPI.

Hypothesis (H<sub>0</sub>): S&P BSE Sensex does not granger cause Wholesale Price Index

Null Hypothesis	Lag Values	Observatio ns	F-statistic	Prob.(p value)	Decision
S&P BSE Sensex does not granger cause Wholesale Price Index	1	59	0.00713	0.9330	Accept
S&P BSE Sensex does not granger cause Wholesale Price Index	2	58	0.12101	0.8863	Accept
S&P BSE Sensex does not granger cause Wholesale Price Index	4	56	0.66427	0.6200	Accept
S&P BSE Sensex does not granger cause Wholesale Price Index	10	50	0.81202	0.6194	Accept
S&P BSE Sensex does not granger cause Wholesale Price Index	14	46	0.94041	0.5405	Accept
S&P BSE Sensex does not granger cause Wholesale Price Index	16	44	2.06834	0.1125	Accept

# (H1): S&P BSE Sensex granger causes Wholesale Price Index.

According to above table, from lag 1 to 16, P-values are more than 0.05. Therefore, the null hypothesis is accepted. Therefore, we can say that Sensex does not help in predicting WPI.

In simple words, Ho: S&P BSE Sensex does not granger cause Wholesale Price Index is accepted.

**Conclusion:** It can be concluded that there exist neither bi-directional nor unidirectional relationship between WPI and BSE Sensex. Since in Case 1 null hypothesis that WPI does not granger cause BSE Sensex is accepted and similarly in case 2 null hypothesis that S&P BSE Sensex

#### INTERNATIONAL JOURNAL OF PROFESSIONAL STUDIES

(IJPS) 2017, Vol. No. 4, Jul-Dec

does not granger cause WPI is accepted. Therefore, it can be concluded that there exist no relationship between two variables.

### 3. Gross Domestic Product and Sensex

Research problem: Whether GDP causes S&P BSE Sensex or/and S&P BSE Sensex causes GDP.

Regression Model for checking Granger causality between two variables is as follow:

• Regression model for IIP causes S&P BSE Sensex

BSE Sensext= $A_{11}$  GDP(t-j) +  $A_{12}$  BSE (t-j) + E (t)

• Regression model for S&P BSE granger causes IIP

 $GDPt = A_{21} GDP (t-j) + A_{22} BSE (t-j) + E (t)$ 

Where, t-j is lagged values or the lag period

E (t): Residual value or the error term

A11, A12, A21, A22 are the coefficients.

# Case 1: GDP does not granger cause S&P BSE Sensex

Hypothesis (H<sub>0</sub>): GDP does not granger cause S&P BSE Sensex

(H1): GDP granger cause S&P BSE Sensex

Null Hypothesis	Lag Values	Observations	F-statistic	Prob.(p value)	Decision
GDP does not granger cause S&P BSE Sensex	1	19	0.11745	0.7363	Accept
GDP does not granger cause S&P BSE Sensex	2	18	0.53932	0.5956	Accept
GDP does not granger cause S&P BSE Sensex	6	14	4909.03	0.0109	Reject

According to above table, at lag1and 2 'p' values is greater than 5% therefore  $H_0$  is accepted. However, when lag value is increased to 6 p-value is 0.0257 which is less than 0.05. Hence, it can thus be interpreted that GDP granger cause S&P BSE Sensex i.e. BSE Sensex can be predicted using GDP.

Ho: GDP does not granger cause S&P BSE Sensex is rejected.

## Case 2: S&P BSE Sensex does not granger GDP.

Hypothesis (H<sub>0</sub>): S&P BSE Sensex does not granger cause GDP.

Null Hypothesis	Lag Values	Observations	F-statistic	Prob.(p value)	Decision
S&P BSE Sensex does not granger cause GDP.	1	19	1.23706	0.7363	Accept
S&P BSE Sensex does not granger cause GDP.	2	18	0.53932	0.5956	Accept
S&P BSE Sensex does not granger cause GDP.	6	14	0.67196	0.7317	Accept

According to above table, for lag values ranging from 0 to 6. P-values are always greater than 0.05. Therefore, null hypothesis that S&P BSE Sensex does not granger cause GDP is accepted and Sensex does not help in predicting GDP.

Ho: S&P BSE Sensex does not granger cause GDP is accepted.

S&P BSE Sensex does not granger cause crude oil prices	1	59	0.41297	0.5231	Accept
S&P BSE Sensex does not granger cause crude oil prices	2	58	0.41090	0.6651	Accept

The base for acceptance or rejection of null hypothesis is comparing the p values with 5% level of significance. If p value is greater than 5% level of significance then null hypothesis is accepted and if 'p' value is less than 5% level of significance then null hypothesis is rejected.

In the above table when lag value is increased from lag 1 to lag 8 it can be observed that p values are significantly higher than the 5% or 0.05, therefore null hypothesis have been accepted or not rejected in all the cases.

Ho: S&P BSE Sensex does not granger cause crude oil prices is not rejected. Thus, S&P BSE Sensex doesn't help in predicting the crude oil prices.

#### Case 2: Crude oil prices does not granger cause S&P BSE Sensex

Hypothesis (H<sub>0</sub>): crude oil prices does not granger cause S&P BSE Sensex

Null Hypothesis	Lag Values	Observations	F-statistic	Prob.(p value)	Decision
S&P BSE Sensex does not granger cause crude oil prices	1	59	0.54213	0.4646	Accept
S&P BSE Sensex does not granger cause crude oil prices	2	58	0.15038	0.8607	Accept

(H1): crude oil prices granger cause S&P BSE Sensex

According to above table, at lag o to 2 'p' value is greater than 5% therefore H<sub>0</sub> is accepted.

Ho: Crude oil prices does not granger cause S&P BSE Sensex is Accepted.

#### **Findings and Limitations**

#### **5.1 Findings**

The primary motive of the present study was to analyze whether there exist granger causality between Macroeconomic variables and BSE Sensex. However, before undertaking this analysis it was essential to check whether the variables under study are stationary or not i.e. whether their mean and variance are invariant with time or show a specific trend. The analysis for checking stationarity or existence of unit root was done using Augmented Dickey Fuller test. The results were as follow:

• All variables including GDP, gold prices, crude oil prices, WPI, BSE Sensex and Index for Industrial production when plotted on graph showed trend and their observations were evolving around a constant called sample mean (Mean value of all the observations) therefore this suggested that stationarity be check at trend and intercept.

• On the basis of above findings augmented dickey fuller test was applied some variables were stationary at first difference and some at  $2^{nd}$  difference i.e. when there is difference between the values and not at level i.e. when there is no difference between the values. Since, all the variables were stationary therefore it can be interpreted that mean and variance for all these variables were time invariant. These findings can be briefly explained in table given below:

Null hypothesis	t-statistic	P value	Decision
S&P BSE Sensex has a unit root	-7.207278	0.0000	Reject
Wholesale Price Index has a unit root	-6.335360	0.0000	Reject
Gross Domestic Product has a unit root	-29.22434	0.0001	Reject
Index for Industrial Production has a unit root	-9.361041	0.0000	Reject
Gold price has a unit root	-29.22434	0.0000	Reject
Crude oil has a unit root	-7.351958	0.0000	Reject

## • UNIT ROOT

(IJPS) 2017, Vol. No. 4, Jul-Dec

e-ISSN: 2455-6270; p-ISSN: 2455-7455

Since it was proved through above analysis that all the variables are stationary; so granger causality test was applied. The data undertaken for the present study was a monthly data ranging from 2009-14 therefore the lag values could range between 1 to 18. The findings of granger causality are depicted in following table:

## • GRANGER CAUSALITY

Null Hypothesis	F-statistic	Prob.(p value)	Findings
S&P BSE Sensex does not granger cause Wholesale Price Index	2.06834	0.1125	Accept(i.e. stock prices does not help in predicting the Wholesale price index and does not causes WPI to fluctuate )
Wholesale Price Index does not granger cause S&P BSE Sensex	0.58408	0.8407	Accept(i.e. WPI does not help in predicting the stock prices and does not causes stock prices to fluctuate )
Gross Domestic Product does not granger cause S&P BSE Sensex	4909.03	0.0109	Reject (GDP causes BSE Sensex and hence help in predicting the future trend of stock prices).
S&P BSE Sensex does not granger cause Gross Domestic Product	0.67196	0.7317	Accept (BSE Sensex does not cause GDP).
S&P BSE Sensex does not granger cause Index for Industrial production	7.11405	0.0100	Reject (Sensex help in predicting or it causes IIP).
Index for Industrial Production does not granger cause S&P BSE Sensex	0.00757	0.9310	Accept (IIP do not help in predicting stock price and hence does not cause stock prices to fluctuate).
S&P BSE Sensex does not granger cause Gold price	1.30010	0.2755	Accept (BSE Sensex does not cause gold price).
Gold price does not granger cause S&P BSE Sensex	1.51110	0.1889	Accept(i.e. gold price does not help in predicting the stock prices and does not causes stock prices to fluctuate )
S&P BSE Sensex does not granger cause Crude oil	0.41090	0.6651	Accept (BSE Sensex does not cause crude oil).
Crude oil does not granger cause S&P BSE Sensex	0.15038	0.8607	Accept(i.e. crude oil does not help in predicting the stock prices and does not causes stock prices to fluctuate )

(IJPS) 2017, Vol. No. 4, Jul-Dec

Granger causality is used to unravel the nature of causal relationship (unidirectional or bidirectional causality) that exists between the stock market and Macroeconomic variable. The findings are as follow:

- 1. **IIP AND SENSEX:** It can be concluded that there exist unidirectional relationship between IIP and BSE Sensex. Since in Case 1 null hypothesis that S&P BSE Sensex does not granger cause IIP is accepted but in case 2 null hypothesis that IIP does not granger cause BSE Sensex is rejected. Therefore, it can be concluded that there exist a relationship between two variables.
- 2. WPI AND SENSEX: It can be concluded that there exist neither bi-directional nor unidirectional relationship between WPI and BSE Sensex. Since in Case 1 null hypothesis that WPI does not granger cause BSE Sensex is accepted and similarly in case 2 null hypothesis that S&P BSE Sensex does not granger cause WPI is accepted. Therefore, it can be concluded that there exist no relationship between two variables.
- 3. **GDP AND SENSEX:** It can be concluded that there exist unidirectional relationship between S&P BSE Sensex and GDP. Since from case 1 null hypothesis the GDP does not granger cause S&P BSE Sensex is rejected i.e. accepted. Hence, it can be concluded that GDP do not cause SENSEX. On the other hand in case 2 null hypothesis that S&P BSE Sensex does not granger cause GDP is rejected hence SENSEX help in GDP. Therefore, there exist unidirectional relationship between S&P BSE Sensex and GDP.
- 4. **GOLD PRICE AND SENSEX:** It can be concluded that there exist neither bi-directional nor unidirectional relationship between Gold prices and BSE Sensex. Since in Case 1 null hypothesis that Gold price does not granger cause S&P BSE Sensex is accepted and similarly in case 2 null hypothesis that S&P BSE Sensex does not granger cause Gold price is accepted. Therefore, it can be concluded that there exist no relationship between two variables.
- 5. **CRUDE OIL AND SENSEX:** It can be concluded that there exist neither bi-directional nor unidirectional relationship between Crude oil and BSE Sensex. Therefore, it can be concluded that there exist no relationship between two variables.

## **5.2 LIMITATIONS**

Since only 5 years have been undertaken for study therefore, their exist no relationship between some variables under study.

e-ISSN: 2455-6270; p-ISSN: 2455-7455

## Conclusion

The key objective of the present study was to explore the impact of different macroeconomic variables on the stock prices in India using monthly data from period 2009 to 2014. In this study; the S&P BSE Sensitive index was used as a proxy for the Indian stock prices. The vital macroeconomic variables included in the study are Gross domestic product (GDP), Whole price index (WPI), Gold prices (GLD), Crude oil prices (OIL) and Index for Industrial Production (IIP).

The primary purpose of the present study was to check for existence of granger causality between Macroeconomic variables and S&P BSE Sensex .However, prior to study of such a relationship it was essential to check whether the variables undertaken for the study are stationary or not. A variable is said to be stationary if the mean and variance are time-invariant i.e. mean [E (Yt)] and the variance [Var (Yt)] of Y remains constant over time for all t. Therefore, a formal test of stationary i.e. Augmented Dickey Fuller test (ADF) was used to test for unit root. Graphical representation of each variable was used to analyze whether the variables depicted any trend or not and whether the observations evolve around constant called sample mean. Variables which depicted existence of both trend and whose observations evolved around mean were studied using trend and intercept. All variables including Gross domestic product, Gold prices, crude oil prices, Whole price index and Index for Industrial production evolved around mean and were following a particular trend.

After it was analyzed using graph whether to undertake the analysis using trend and intercept the econometric model was applied. Results showed stationary of all the variables at first difference and  $2^{nd}$  difference and not at level. Since analysis of all the variables depicted stationarity therefore granger causality test could be applied.

Granger causality test is a technique for determining whether one time series is significant in forecasting another i.e. whether past values of variables help to predict changes in another variable. If there are two variables X and Y, then variable Y is granger caused by X if variable X assists in predicting the value of variable Y. The null hypothesis that we test in this case is that X does not granger cause Y and Y does not granger cause X.

The estimates of multivariate granger causality indicate that there exists unidirectional causality between Gross Domestic Product and BSE Sensex i.e. GDP causes BSE Sensex and not vice versa, Index for Industrial Production and BSE Sensex i.e. BSE Sensex causes IIP and not vice versa. There exist no causal relationship between BSE Sensex and Wholesale Price Index (WPI).On the other hand, that there exists neither bi-directional nor unidirectional relationship between Crude oil prices (OIL) nor Gold prices.

The results have implication on domestic as well as foreign investors, stock market regulators, policy makers and stock market analysts. Investors and stock market analysts could forecast stock

(IJPS) 2017, Vol. No. 4, Jul-Dec

prices using mix of all the variables and hence can undertake buying or selling decision. The quantitative data analyzed in present study well relates with the perception of investors in the stock market and the qualitative data that is being presented in the news and media. The relationship between BSE Sensex and Macroeconomic variable could be well seen when we come across newspaper headlines of bullish and bearish market. Hence, it could be concluded that both Quantitative and Qualitative data depicts relationship between macroeconomic variable and BSE Sensex.
